

Community-Monitoring Screening

Independent screening shortlist | GHSL 2020 modelled population context in each individual 5 km buffer

Community-monitoring candidates

24 selected sites; values are not summed because buffers overlap

How to read this map

Selection applies the locked flare-evidence gate (recent volume $\geq$ P75 and $\geq$ 10 positive-volume years) plus population context $\geq$ P75 (39,298 people). GHSL values are modelled 2020 population counts per native grid cell, summed within each individual geodesic 5 km buffer.

Critical limit

Overlapping buffers must not be summed as unique people, and the context does not measure exposure or health effects.

Context year: 2020
